

# Plain XML Message Responder

This is one the most common types of Message Responder.

It simplifies the use of XML by providing a form view for configuring responses from elements defined in an XML schema (XSD). Each Message Responder responds to incoming request messages that match its Responder Correlation criteria. Responses can be configured in a variety of modes, ranging from simple fixed messages to dynamic parameterized messages using a data source. Message Responders are protocol agnostic, but the transport protocol or API to access a responder is defined in the deployment configuration of the PVA.

You can create a Plain XML Message Responder tool directly from the Add Responder wizards. This responder is preconfigured as follows:

Setting	Configuration
Resource Mode	Schema Service Definition
XML Message Type	Plain XML
Response tab view	Form Input

Form Input mode allows you to define and parameterize plain XML payloads via a graphical interface (as described in [Form Input View Options](#)).

All of the available configuration options for this type of message responder are covered in [Message Responder Overview](#).
