

# JSON Message Responder

This is one the most common types of Message Responders.

It simplifies the use of JSON (JavaScript Object Notation) by providing a form view for configuring responses. Each Message Responder responds to incoming request messages that match its Responder Correlation criteria. Responses can be configured in a variety of modes, ranging from simple fixed messages to dynamic parameterized messages using a data source. Message Responders are protocol agnostic, but the transport protocol or API to access a responder is defined in the deployment configuration of the PVA.

You can create a JSON Message Responder tool directly from the Add Responder wizards. This responder is preconfigured as follows:

Setting	Configuration
Resource Mode	No Service Definition
Response tab view	Form JSON

Form JSON input mode allows you to define and parameterize JSON payloads via a graphical interface (as described in [Form JSON View Options](#)).

All of the available configuration options for this type of message responder are covered in [Message Responder Overview](#).

For tips on virtualizing JSON services, see [Using JSON](#).
